4rd International Conference on Web Information Systems Engineering (WISE 2003),  
December 10th to 12th, 2003,  
Rome, Italy.

# Our Focus (1)

- Web services and their composition into Web Processes promise to power eCommerce and eServices
- Supporting Web Processes on multi-enterprise and Web scale require addressing heterogeneity/integration, scalability, dynamic change and performance challenges
- Semantics is seen as the key enabler to address these challenges; Semantic Web Processes build upon Web Services and Semantic Web technologies
- This tutorial is about adding *semantics* to **Web Services**, and exploiting them in **Web Process Lifecycle (Specification, Discovery, Composition, Execution)**
  - Functional perspective takes form of process composition involving **Web Service Discovery**, addressing semantic heterogeneity handling
  - Operational perspective takes form of the research on **QoS Specification** for Web Services and Processes.

# Our Focus (2)

## Semantics

### Web Processes

**Web Process Composition**

**Web Process QoS**

### Web Services

**Web Service Annotation**

**Web Service Discovery**

**Web Service QoS**

# The Basics

**What are  
Web Services,  
Web Processes,  
and Semantics?**

# Web Services: Definition

## Web Services

“Web services are a new breed of Web application. They are **self-contained**, **self-describing**, modular applications that can be **published**, **located**, and **invoked** across the Web. Web services perform functions, which can be anything from simple requests to complicated business processes. ...

Once a Web service is deployed, other applications (and other Web services) can discover and invoke the deployed service.”

# Why Web Services?

## Web Services

Jini

Enterprise Java Beans

RMI (Remote Method Invocation)

Microsoft DCOM

CORBA (Common Object Request Broker Architecture)

Open Software Foundation DCE (Distributed Computing Environment)

Sun ONC/RPC (Open Network Computing)

IP, UDP, TCP

# Why Web services?

## Web Services

Feature	CORBA	Web Services
Data Model	Object Model	SOAP Message exchange model
Client Server Coupling	Tight Coupling	Loose Coupling
Parameter Passing	Pass by reference/value	Pass by value only
Type Checking	1. Static + Runtime type checking (Regular) 2. Runtime type checking only (DII)	RunTime type checking only
State	Stateful	1. Stateless, Uncorrelated (Web Services) 2. Stateful (Web Process)
Firewall Traversal	Work in Progress	Uses HTTP port 80
Service Discovery	CORBA naming/trading Service	UDDI
Communication Mode	1-way, 2-way sync 2-way async	2-way sync (Web Services) 1-way, 2-way sync, 2-way async (Web Process)

# What are Web Processes (1)?

- **Web Processes** are next generation workflow technology to facilitate the interaction of organizations with markets, competitors, suppliers, customers etc. supporting enterprise-level and core business activities
  - encompass the ideas of both intra and inter organizational workflow.
  - created from the composition of Web services
- When all the tasks involved in a Web process are semantically described, we may call such process as **Semantic Web Processes**

# What are Web Processes ? (2)

## Web Processes

- Web processes describe **how Web services are connected** to create reliable and dependable business solutions
- Web processes allow businesses to describe sophisticated processes that can both consume and provide Web services
- The role of Web processes within the enterprise is to simplify the **integration** of business and application processes across technological and corporate domains

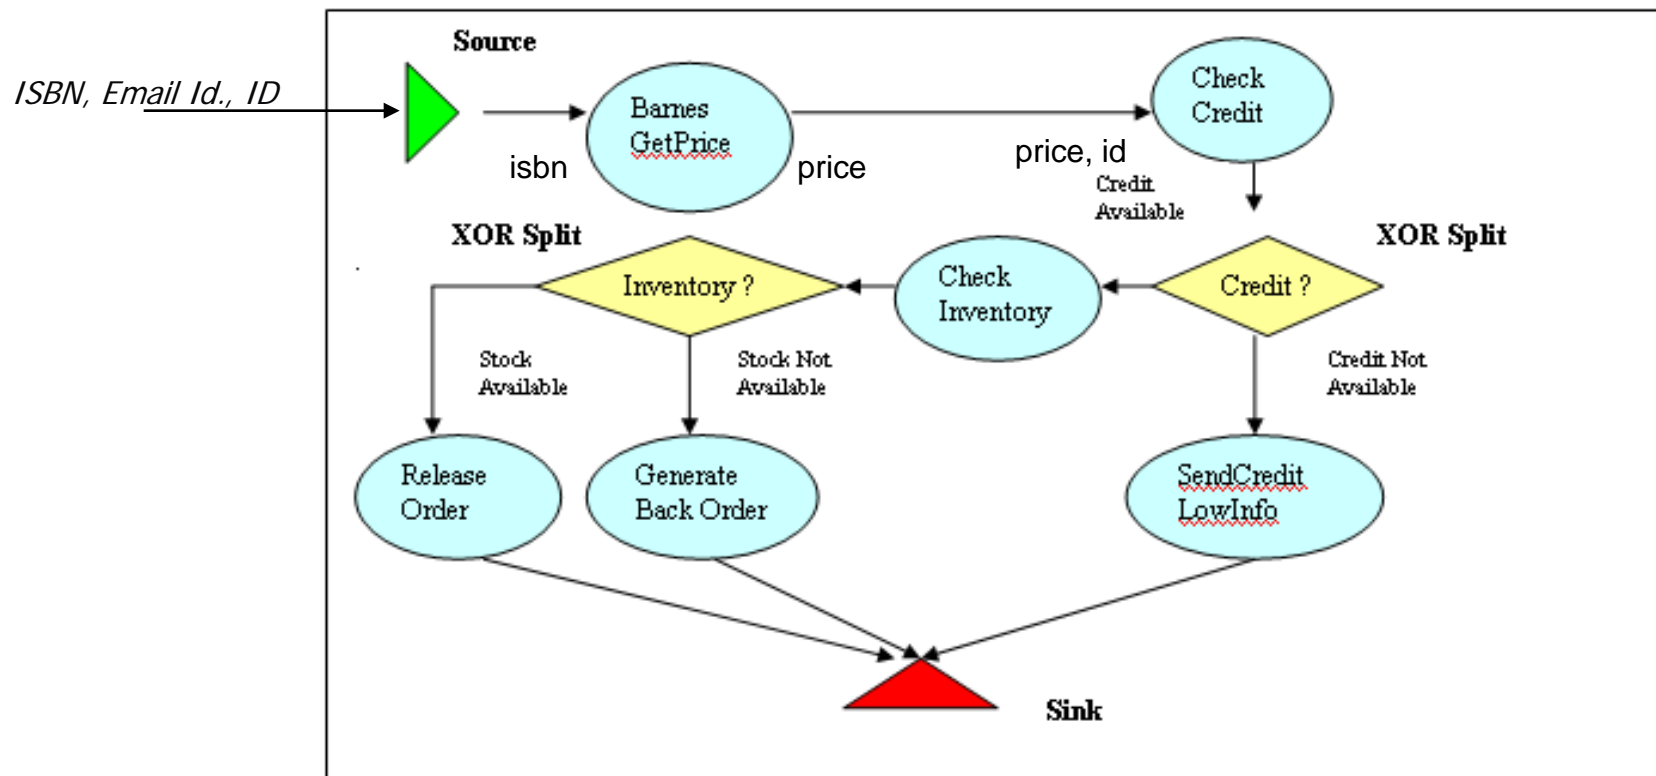

# Web Process

## An Example

## Web Processes

Inter-Enterprise

Global

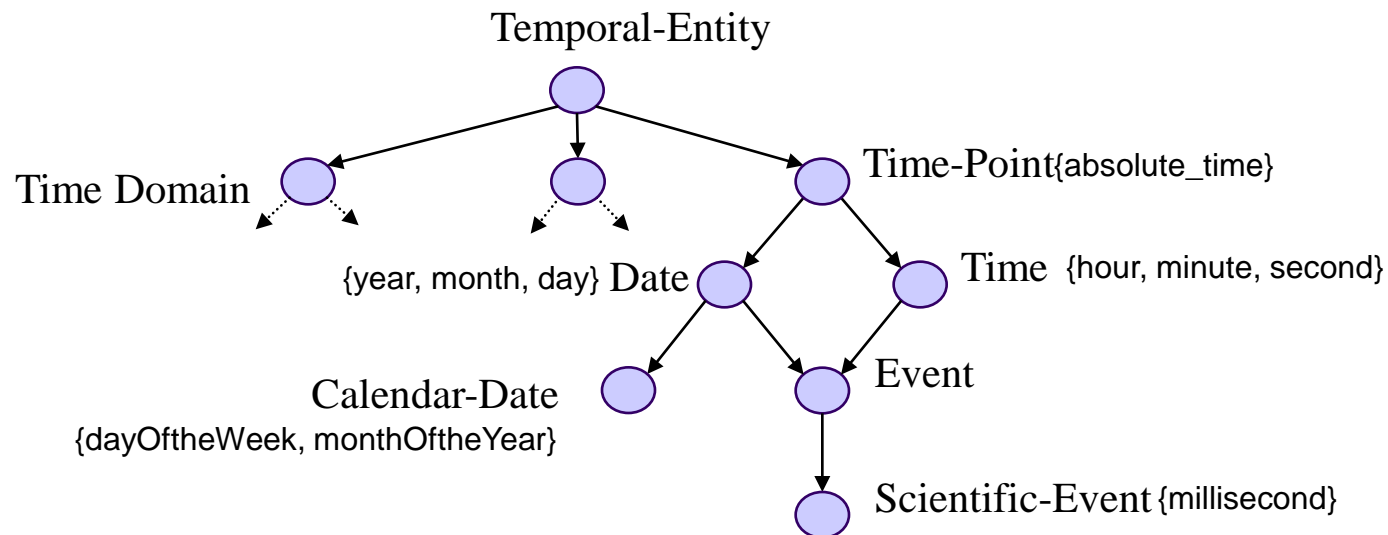

# BIG Challenges

- **Heterogeneity and Autonomy**
  - Syntactic, semantic and pragmatic
  - Complex rules/regulations related to B2B and e-commerce interactions
  - Solution: Machine processable descriptions
- **Dynamic** nature of business interactions
  - Demands: Efficient Discovery, Composition, etc.
- **Scalability** (Enterprises → Web)
  - Needs: Automated service discovery/selection and composition

Proposition: **Semantics** is the most important enabler to address these challenges

# What are Semantics and Ontologies?

- An ontology includes a **vocabulary of terms**, and some **specification of their meaning**.
- The goal is to create an **agreed-upon vocabulary** and semantic structure for exchanging information about that domain.

# Roadmap

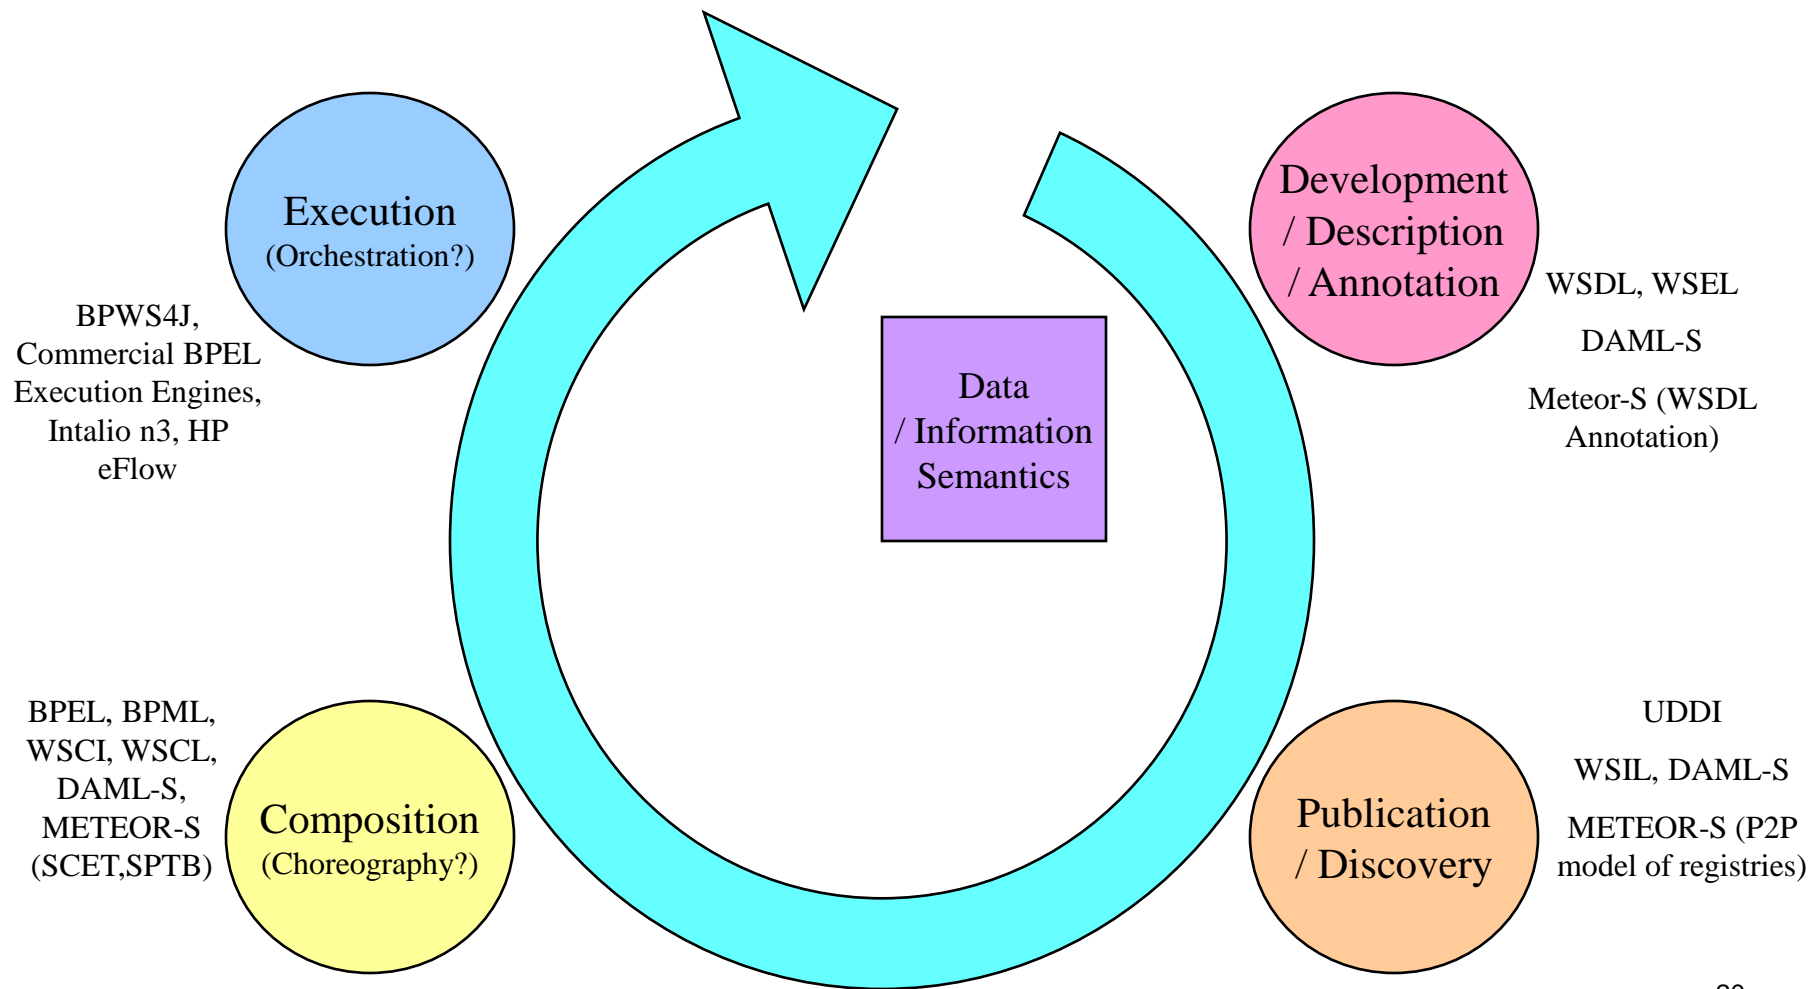

# Semantics for Web Processes

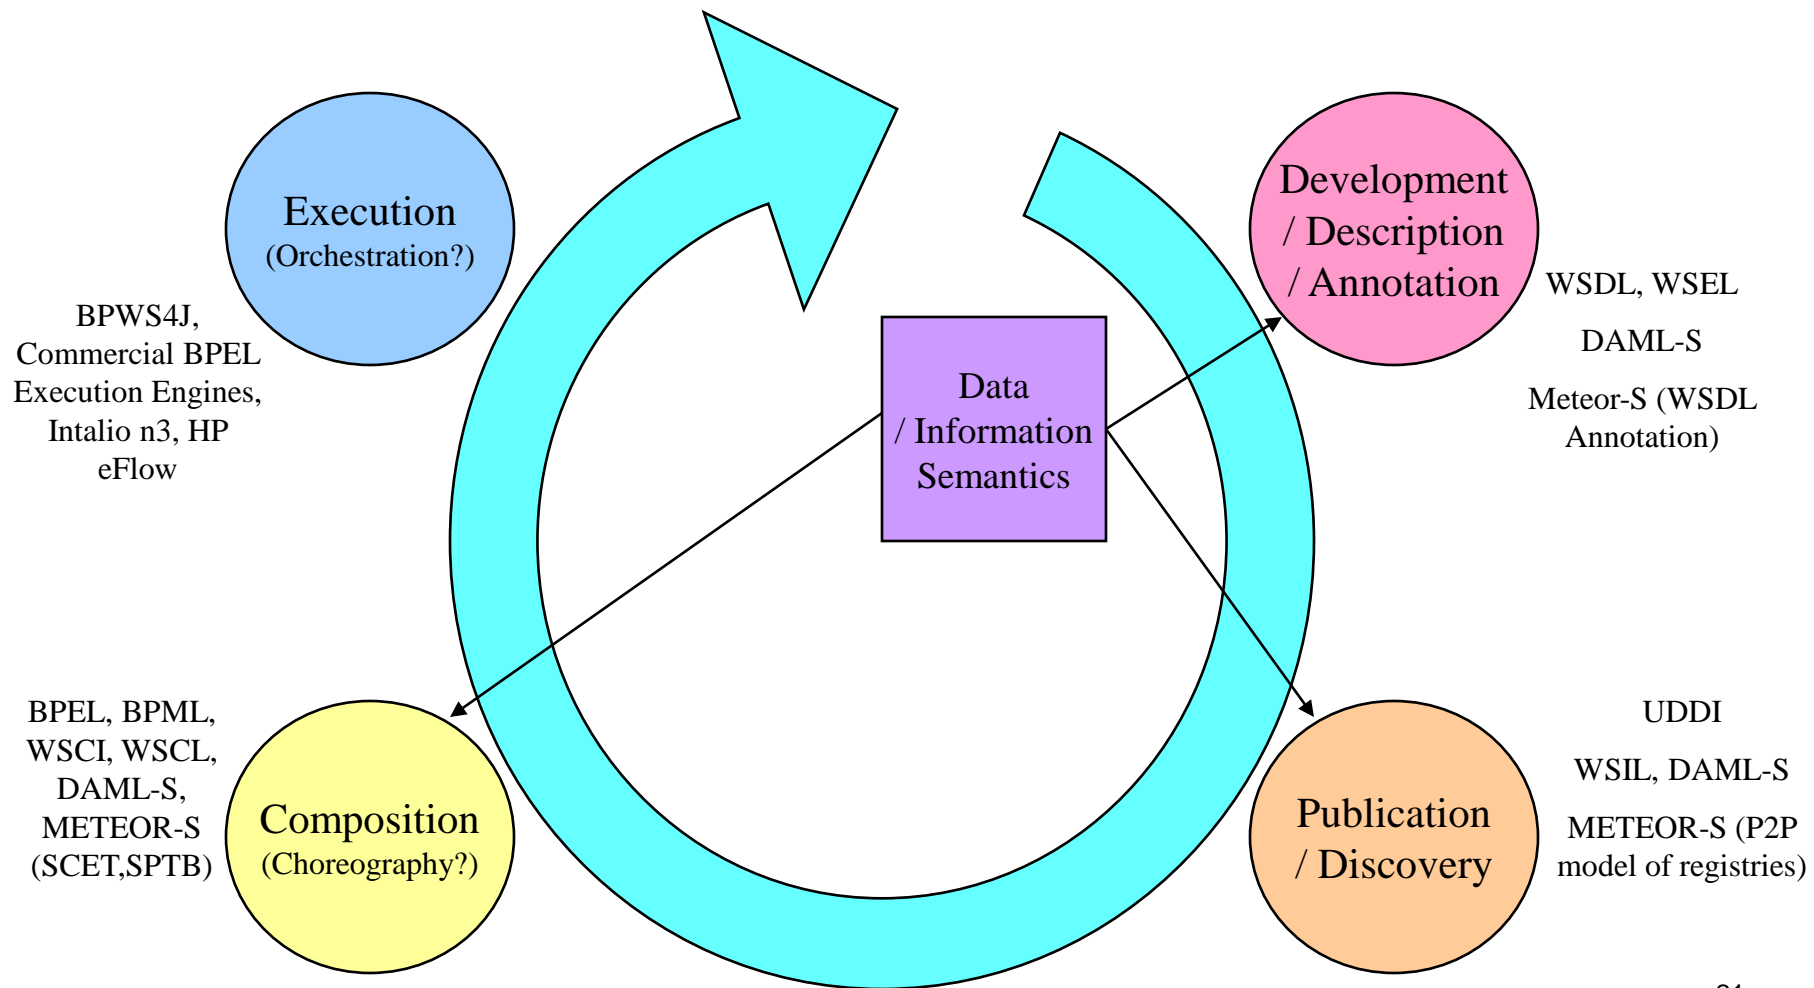

- **Data/Information Semantics**
  - **What:** Formal definition of data in input and output messages of a web service
  - **Why:** for discovery and interoperability
  - **How:** by annotating *input/output data* of web services using ontologies
- **Functional/Operational Semantics**
  - Formally representing capabilities of web service
  - for discovery and composition of Web Services
  - by annotating *operations* of Web Services as well as provide *preconditions* and *effects*; Annotating *TPA/SLA* (*future work*)
- **Execution Semantics**
  - Formally representing the execution or flow of a services in a process or operations in a service
  - for analysis (verification), validation (simulation) and execution (exception handling) of the process models
  - using *State Machines*, *Petri nets*, *activity diagrams* etc.
- **QoS Semantics**
  - Formally describing operational metrics of a web service/process
  - To select the most suitable service to carry out an activity in a process
  - using *QoS model* [Cardoso and Sheth, 2002] for web services

Semantics

# Web Process Architecture

## Web service Semantic Annotation

Associate ontological concepts  
to Web service descriptions

Adding Semantics to Web Services Standards , Semantic Annotation of Web Services

**Semantics**

# Web Services

## Web Service

- **WSDL** defines services as collections of network endpoints or *ports*. A port is defined by associating a network address with a binding; a collection of ports define a service.
- **SOAP** is a message layout specification that defines a uniform way of passing XML-encoded data. It also defines a way to bind to HTTP as the underlying communication protocol. SOAP is basically a technology to allow for “RPC *over the web*”.
- **XML** was designed to describe data and to focus on what data is.

# WSDL

## Web Service

- WSDL stands for Web Services Description Language
- WSDL is an XML document
- WSDL is used to describe Web services
- WSDL is also used to locate Web services

# WSDL

## Web Service

<definitions>

```
<types>
    definition of types..
</types>

<message>
    definition of messages...
</message>

<portType>
    <operation> ..... </operation>
    <operation> ..... </operation>
</portType>
```

**Abstract  
Description**

```
<binding>
    definition of binding....
</binding>

<service>
    <port>....</port>
    <port>....</port>
</service>
```

**Concrete  
Description**

</definitions>

# Semantic Annotation of Web Services

## Annotation of Web Services

- To enhance the discovery, composition, and orchestration of Web services, it is necessary to increase the description of their interfaces.
- One solution is to annotate WSDL interfaces with semantic metadata based on relevant ontologies.

An ontology is a specification of a representational vocabulary for a shared domain of discourse.

# Semantics at Description Layer

## Description Layer:

### Why:

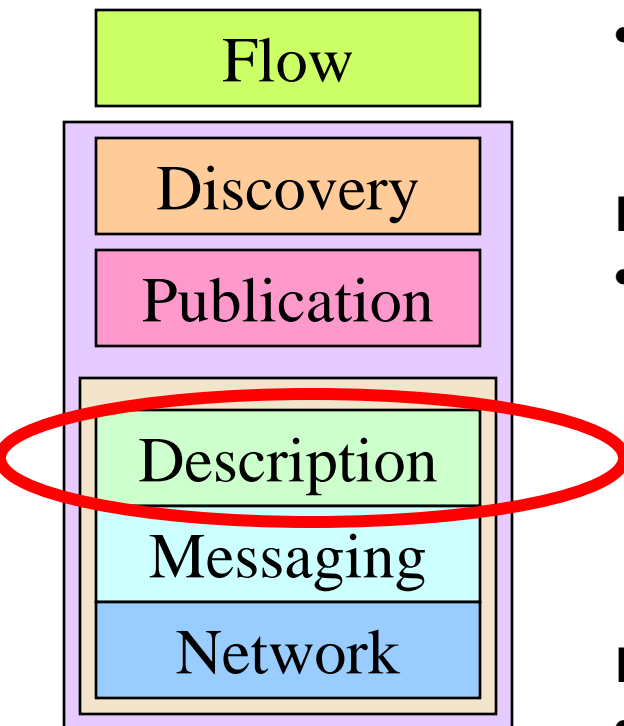

- Unambiguously understand the **functionality** of the services and the semantics of the operational **data**

### How:

- Using Ontologies to semantically annotate WSDL constructs (conforming to extensibility allowed in WSDL specification version 1.2) to sufficiently explicate the semantics of the
  - **data types** used in the service description and
  - **functionality** of the service

### Present scenario:

- WSDL descriptions are mainly syntactic (provides operational information and not functional information)
- Semantic matchmaking is not possible

# How to Annotate ?

- Map Web service's input & output data as well as functional description using relevant data and function/operation ontologies, respectively 
- How ?
  - Borrow from schema matching
  - Semantic disambiguation between terms in XML messages represented in WSDL and concepts in ontology

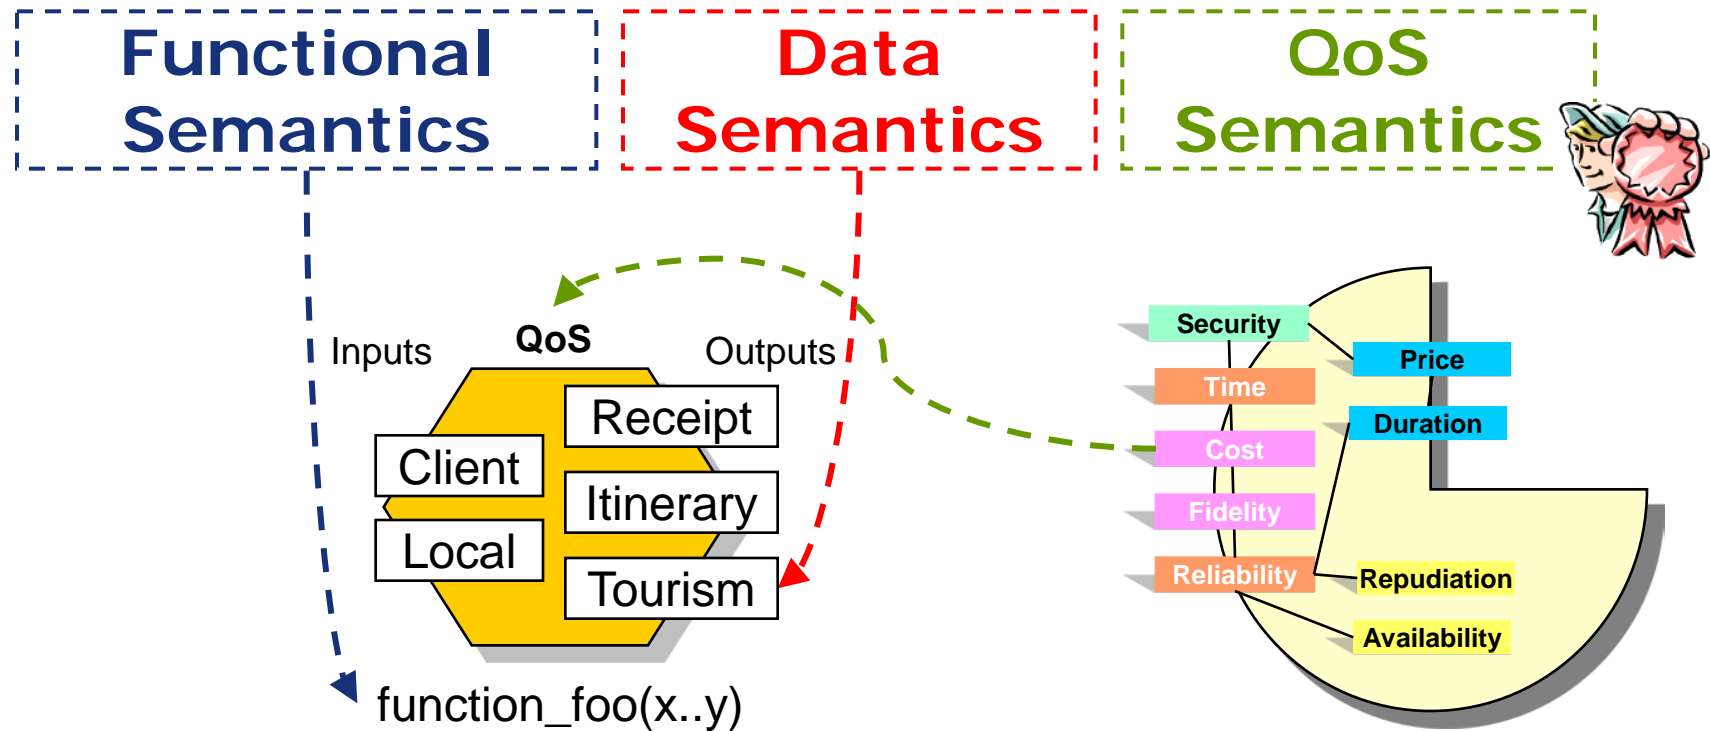

# Web Services Interfaces

- A Web service (WS) invocation specifies:
  - The number of input parameters that must be supplied for a proper WS realization and
  - The number of outputs parameters to hold and transfer the results of the WS realization to other tasks.
  - A function to invoke

# Types of Annotation

# Adding Semantics to Web Services

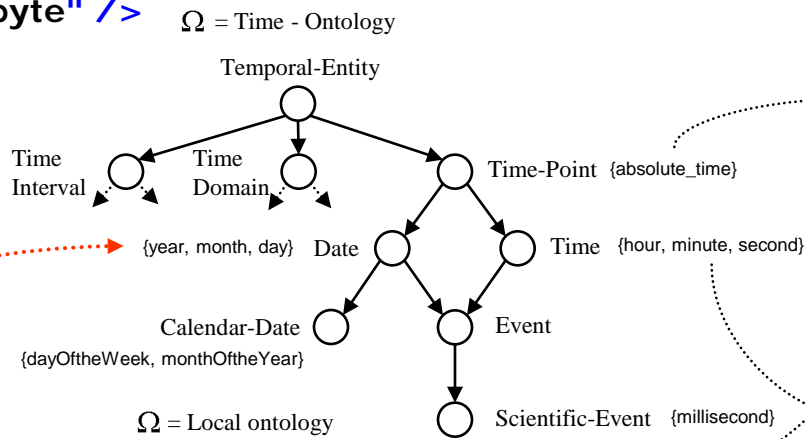

```
<xsd:complexType name="Date">
  <xsd:sequence>
    <xsd:element name="year" type="xsd:integer" />
    <xsd:element name="month" type="xsd:integer" />
    <xsd:element name="day" type="xsd:byte" />
  </xsd:sequence>
</xsd:complexType>
```

    <ssn>123-456-7890</ssn>  
  </v:DoCreditCheck>  
</SOAP:Body>
```

```
</SOAP:Envelope>
```

Header

Body

# Why SOAP?

- Today's applications communicate using Remote Procedure Calls (RPC) between objects like DCOM and CORBA
- RPC represents a compatibility and security problem; firewalls and proxy servers will normally block this kind of traffic.
- A better way to communicate between applications is over HTTP, because HTTP is supported by all Internet browsers and servers. SOAP was created to accomplish this.

# SOAP - Annotation

```
<soap:Body>
```

```
<m:GetPrice xmlns:m="http://www.w3schools.com/prices">

# Web Process Architecture

## Semantic Brokering

Specialized brokering services to find Web services

## Semantic Discovery

Discovery algorithms that account for semantic information

## Semantic Registries

Describe Web services in UDDI registries using semantic concepts

METEOR-S

Brokering

Discovery

UDDI

Semantics

Semantics

Semantics

Semantics

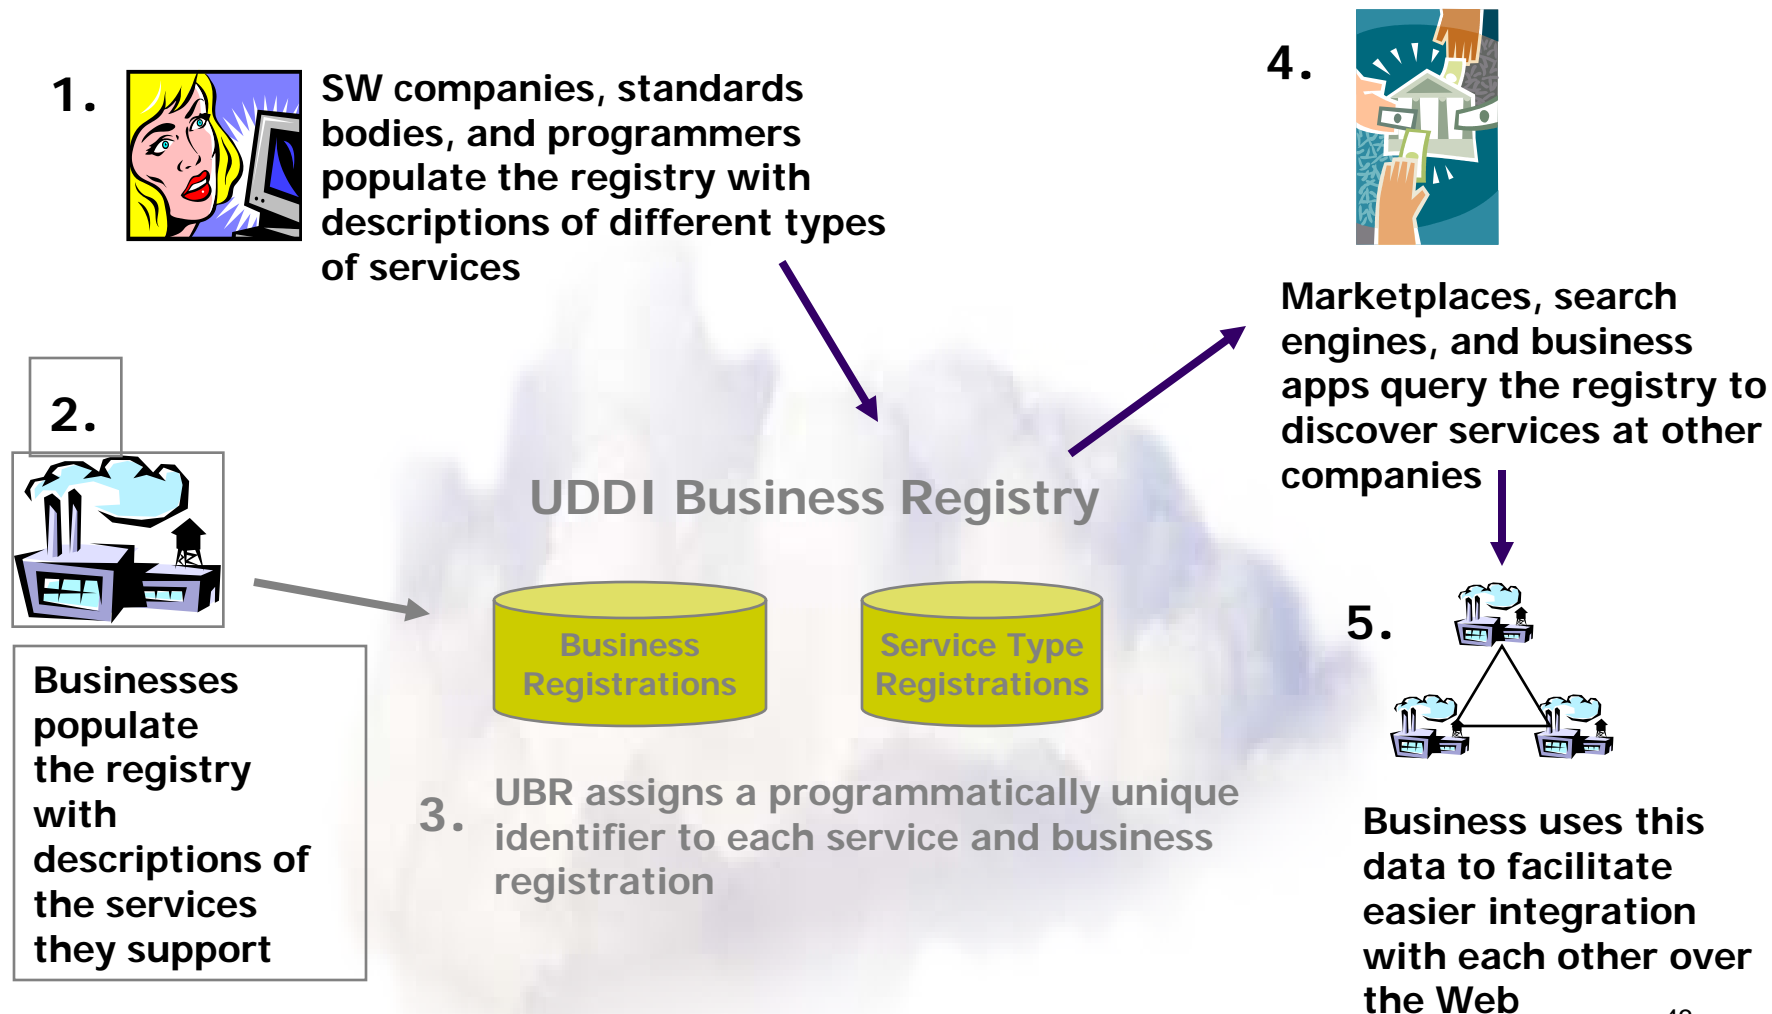

# UDDI

- **UDDI** stands for Universal Description, Discovery and Integration
- **UDDI** serves as a “Business and services” registry and directory and are essential for dynamic usage of Web services
- A **UDDI** registry is similar to a CORBA trader, or it can be thought of as a DNS for business applications.
- Is a platform-independent framework for describing services, discovering businesses, and integrating business services by using the Internet.

# How UDDI Works ?

# Semantics at Publication and Discovery Layers

## Publication and Discovery Layers:

### Why:

- Enable scalable, efficient and dynamic publication and discovery (machine processable / automation)

### How:

- Use of ontology to categorize registries based on domains and characterize them by maintaining the
  1. **properties** of each registry
  2. **relationships** between the registries
- Capturing the WSDL annotations in UDDI

### Present scenario:

- Suitable for simple searches ( like services offered by a provider, services that implement an interface, services that have a common technical fingerprint etc.)
- Categories are too broad
- Automated service discovery (based on functionality) and selecting the best suited service is not possible

# UDDI and Semantics

# State of the art in discovery

## UDDI Business Registry

Provides non-semantic search

## Search

Keyword and  
attribute-based  
match

## Results

Search retrieves lot of  
services (**irrelevant**  
results included)

Which service to select ?  
How to select?

## Selection

# Present Discovery Mechanism

## Keyword and attribute-based search

### Web Service Discovery

- UDDI :Keyword and attribute-based search
- Example: “Quote”
  - Microsoft UBR returned 12 services
  - Human reading of description (Natural Language) help me understand:
    - 6 Entries are to get Famous Quotes
    - 1 Entry for personal auto and homeowners quoting
    - 1 Entry for multiple supplier quotes on all building materials
  - Categorization suggested for UDDI is useful but inadequate (what does the WS do?) :
    - 1 Entry for Automobile Manufacturing
    - 1 Entry for Insurance agents, brokers, & service
  - Alternatively read and try to understand WSDL
    - 1 Entry related to security details (Human Understanding)
    - 1 Test Web service for Quotes (which quote?)

# Present Discovery Mechanism

## Search for services to book an air ticket (using categories)\*

- unspsc-org: unspsc:3-1
  - Travel, Food, Lodging and Entertainment Services
    - Travel facilitation
      - Travel agents
        - Travel agencies
- Services: 3 records found.
  - AirFares
    - Returns air fares from netviagens.com travel agent
  - Hotel reservations
    - Reservations for hotels in Asia, Australia and New Zealand
  - Your Vacation Specialists
    - Web enabled vacation information
- Providers: 2 records found.

\* Search carried out in one of the Universal Business Registries

# Present Discovery Mechanism

## Search for services to book an air ticket (using Keywords)\*

- air ticket
  - 1 record with name **air tickets booking**
- airticket, ticketbooking, airtravel, air travel, travel agent, airticketbooking, air ticket booking, travel agency, travelagency
  - 0 records were returned
- travelagent
  - 1 record with name **travelagent test**
    - 4 services: BookFlight, cancelFlightBooking etc.
    - Descriptions say that both these services are “XML based Web services”
    - No URL for WSDL
- Travel
  - 15 records. Purpose/functionality **understood** from **descriptions**
    - 2 services : TravelBooks
    - 4 services : TravellInformation
    - 2 services : Reservation and cancellation of travel tickets
    - 1 service : Emergency Services for travellers
    - 1 service : Travel documentation and itinerary
    - 5 services : Description is ambiguous/not present

# The use of semantics

## Benefits

### Web Service Discovery

- Search engines can better “understand” the contents of a particular page
- More accurate searches
- Additional information aids precision
- Makes it possible to automate searches because less manual “weeding” is needed to process the search results
- Facilitates the integration of several Web services

# Semantic Discovery: Overview

- Annotation and Publication
  - WSDL file is **annotated** using ontologies and the annotations are captured in UDDI
- Discovery
  - Requirements are captured as **templates** that are constructed using ontologies and semantic matching is done against UDDI entries
    - Functionality of the template, its inputs, outputs, preconditions and effects are represented using ontologies
- Use of ontologies
  - brings service provider and service requestor to a **common conceptual space**
  - helps in **semantic matching** of requirements and specifications

# Discovery in Semantic Web Using Semantics

## Web Service Discovery

- **Functionality:** What capabilities the distributor expects from the service  
(Functional semantics)
- **Inputs:** What the distributor can give to the to the Manufacturer's service  
(Data semantics)
- **Outputs:** What the distributor expects as outputs from the service  
(Data semantics)
- **QoS:** Quality of Service the distributor expects from the service  
(QoS semantics)

(Functional semantics)  
(Data semantics)  
(QoS semantics)  
(Syntactic description)

- **Description:** Natural language description of the service functionality  
(Syntactic description)

Brokering

Specifications

Specifications

# Semantic Brokering Issues

- Structured and non-structured sources
- Read-only
- Transparency
  - Location, schema, language, and ontologies
- Global schema
  - Support for semantic schema integration
- Query models
  - Semantic-based, rule-based, SQL-like, etc
- Semantic Mediators
  - Semantic query analysis and query processing
  - Use wrappers

# Brokering and Semantics

- Find Web services across several UDDIs
- Specialized and optimized brokers for specific domain search
  - Transports, Finances, Education, etc.
- Allow the interpretation of complex requirements
  - Domain semantics
  - Functional semantics
  - Data semantics
  - QoS semantics

# Web Process Architecture

## Semantic Composition

Semantic algorithms to  
compute degree Web services integration

Semantics

# Semantic Process Composition

## Web Process Composition

**Composition** is the task of combining and linking existing Web Services and other components to create new processes.

### Types of Composition

- **Static Composition** - services to be composed are decided at design time
- **Dynamic Composition** - services to be composed are decided at run-time

# Composition of Web Processes

## Web Process Composition

Web Process

Composition

### Web Service Discovery

Once the desired Web Services have been found (**Discovery**), mechanisms are needed to facilitate the resolution of structural and semantic differences (**integration**)

### Web Service Integration

This is because the heterogeneous Web services found in the first step need to **interoperate with other components** present in a process host

# Semantics at Flow Layers

## Flow Layer:

### Why:

- Design (composition), analysis (verification), validation (simulation) and execution (exception handling) of the process models
- To employ mediator architectures for automated composition, control flow and data flow based on requirements
- To employ user interface to capture template requirements and generate template based on that

### How:

- Using
  - **Functionality/preconditions/effects** of the participating services
  - Knowledge of **conversation patterns** supported by the service
  - Formal mathematical models like **process algebra**, concurrency formalisms like **State Machines**, **Petri nets** etc.
  - **Simulation** techniques

### Present Scenario:

- Composition of Web services is static.
- Dynamic service discovery, run-time binding, analysis and simulation are not supported directly

# Integration

## New Requirements

### Web Process Composition

- When Web services are put together
  - Their interfaces need to interoperate.
  - Structural and semantic heterogeneity need to be resolved\*.
- **Structural heterogeneity** exists because Web services use different data structures and class hierarchies to define the parameters of their interfaces.
- **Semantic heterogeneity** considers the intended meaning of the terms employed in labeling interface parameters. The data that is interchanged among Web services has to be understood.

\* [Kashyap and Sheth 1996](#)

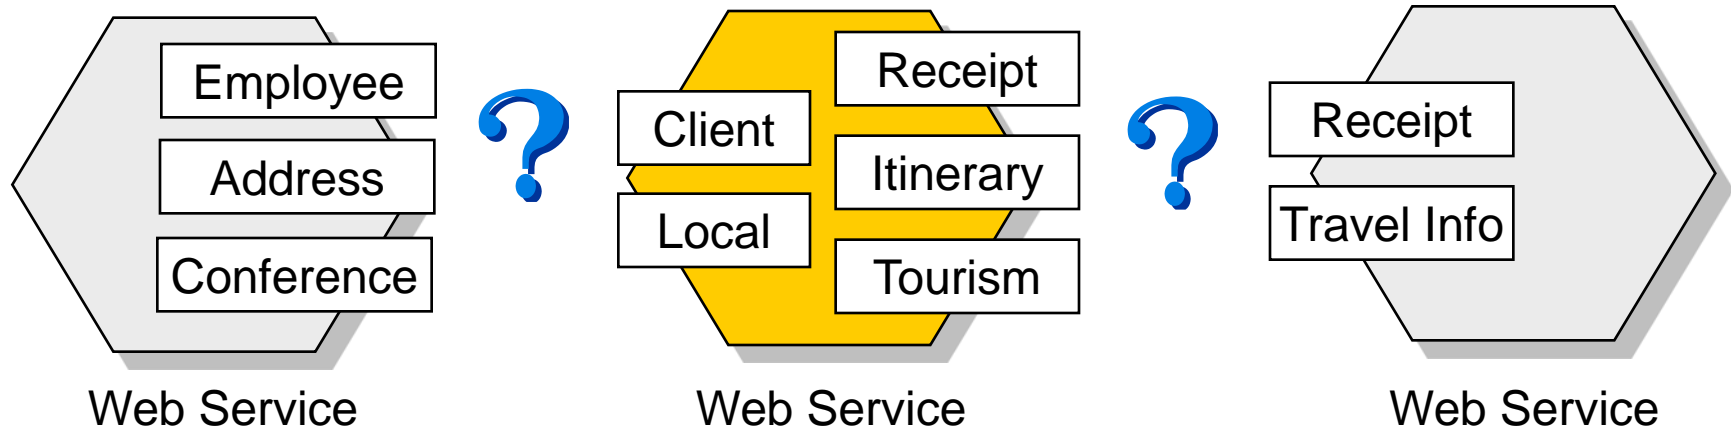

# Integration

## New Requirements

### Web Process Composition

How to establish data connections between Web Services interfaces?

How to establish data connections between the different data structures and class hierarchies of the interface parameters?

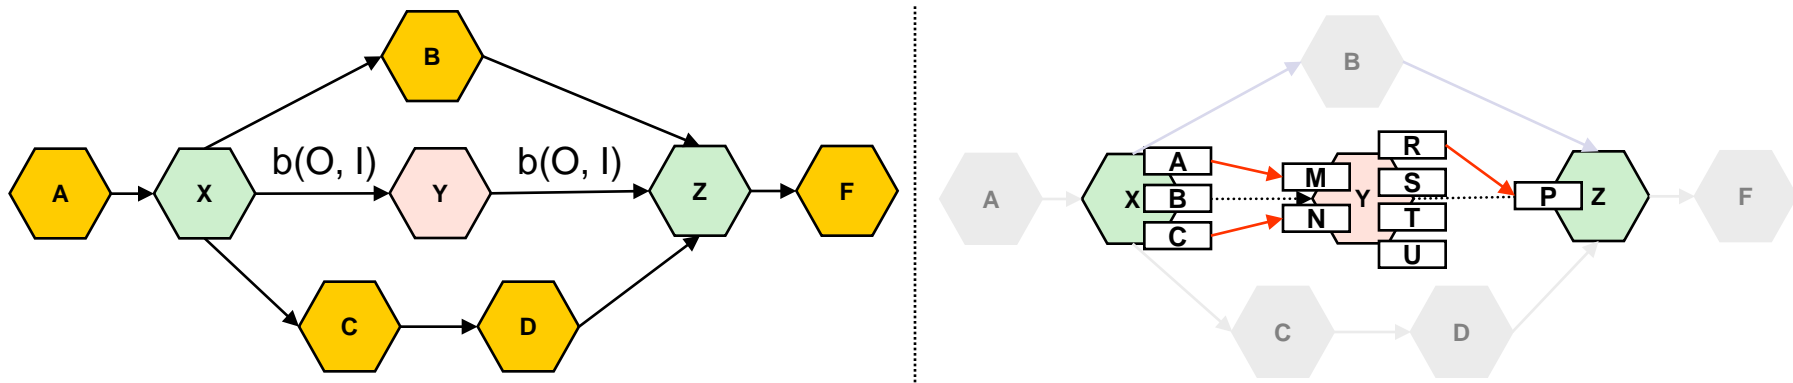

How to understand the intended meaning of the terms used in labeling interface parameters?

# Web Services Interfaces

## Web Process Composition

- To enhance the integration, Web services need to have their inputs and outputs associated with ontological concepts (annotation).
- This will facilitate the resolution of structural and semantic heterogeneities
- Compute the optimal matching (Bondy and Murty, 1976) using semantic information (Cardoso and Sheth, 2002)

Bipartite graph. Each edge has a weight (semantic similarity).

# Semantic Web Processes

## Questions?

# Semantic Web Processes

## Coffee Break

10 Minutes

**NEXT:** Composition Languages

**NEXT:** METEOR-S

# Composition Languages

- BPEL4WS
- DAML-S

# BPEL4WS

## Introduction

## BPEL4WS

- BPEL4WS (Business Process Execution Language for Web Services) is a **process modeling language**.
  - Developed by IBM, Microsoft, and BEA
  - Version 1.1, 5 May 2003
- It supercedes XLANG (Microsoft) and WSFL(IBM).
- It is build on top of WSDL.
  - For descriptions of what services do and how they work, BPEL4WS references port types contained in WSDL documents.

# Web Services Specification

- DAML-S The service profile ontology describes the functionality of a Web service.

# BPEL4WS

## Introduction

- BPEL4WS was released along with two others specs:
  - WS-Coordination and WS-Transaction\*.
- **WS-Coordination** describes how services can make use of pre-defined coordination contexts to subscribe to a particular role in a collaborative activity.
- **WS-Transaction** provides a framework for incorporating transactional semantics into coordinated activities.

\*<http://www-106.ibm.com/developerworks/webservices/library/ws-coor/>,  
<http://www-106.ibm.com/developerworks/webservices/library/ws-transpec/>

# BPEL4WS

## Introduction

- BPEL4WS is a **block-structured programming language**, allowing recursive blocks but restricting definitions and declarations to the top level.
- The language defines **activities** as the basic components of a process definition.
- Structured activities prescribe the order in which a collection of activities take place.
  - Ordinary sequential control between activities is provided by **sequence**, **switch**, and **while**.
  - Concurrency and synchronization between activities is provided by **flow**.
  - Nondeterministic choice based on external events is provided by **pick**.

# BPEL4WS

## Introduction

- Process instance-relevant data (**containers**) can be referred to in routing logic and expressions.
- BPEL4WS defines a mechanism for **catching** and **handling faults** similar to common programming languages, like Java.
- One may also define a **compensation handler** to enable compensatory activities in the event of actions that cannot be explicitly undone.
- BPEL4WS does **not support nested process definition**.

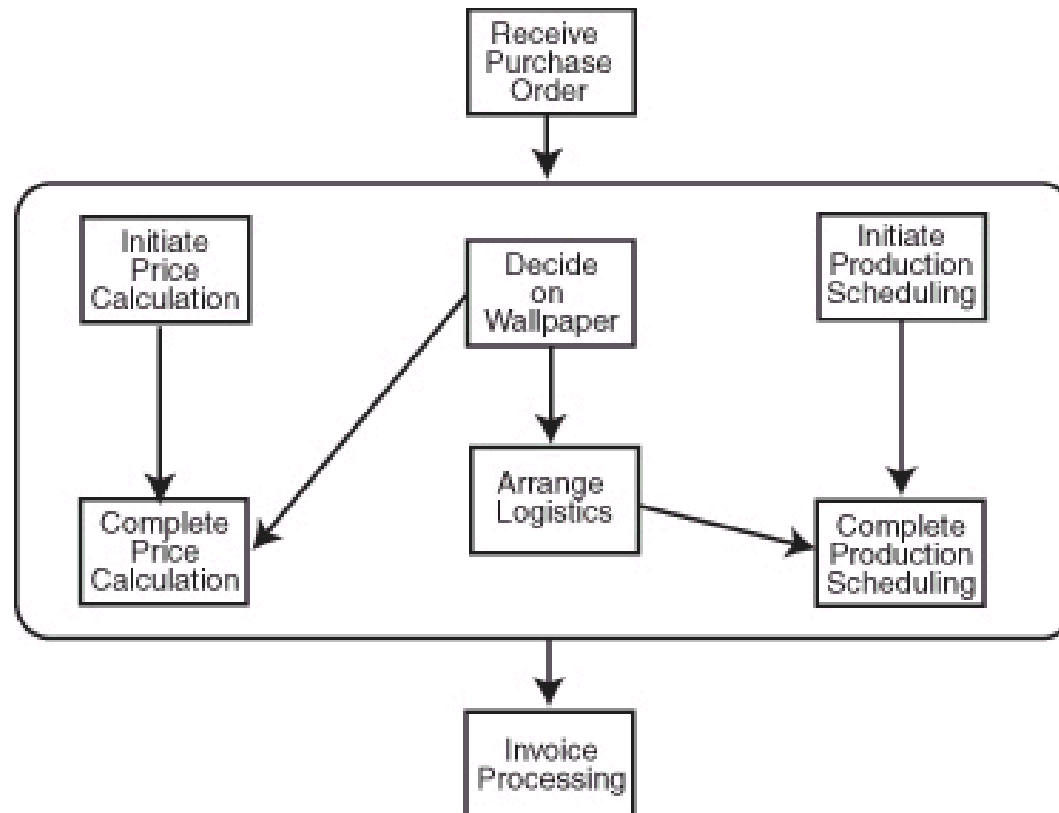

# BPEL4WS

## An Example

Let consider the following process.

# BPEL4WS

## An Example – WSDL definitions

```
<definitions targetNamespace="http://manufacturing.org/wsdl/purchase"
  xmlns:sns="http://manufacturing.org/xsd/purchase"
```

```
...
<message name="POMessage">
  <part name="customerInfo" type="sns:customerInfo"/>
  <part name="purchaseOrder" type="sns:purchaseOrder"/>
</message>
```

```
...
<message name="scheduleMessage">
  <part name="schedule" type="sns:scheduleInfo"/>
</message>
```

Messages

```
<portType name="purchaseOrderPT">
  <operation name="sendPurchaseOrder">
    <input message="pos:POMessage"/>
    <output message="pos:InvMessage"/>
    <fault name="cannotCompleteOrder"
      message="pos:orderFaultType"/>
  </operation>
</portType>
```

The WSDL portType offered by the service to its customer

```
...
<slnk:serviceLinkType name="purchaseLT">
  <slnk:role name="purchaseService">
    <slnk:portType name="pos:purchaseOrderPT"/>
  </slnk:role>
</slnk:serviceLinkType>
```

Roles

```
...
</definitions>
```

# BPEL4WS

## An Example – The process

```
<process name="purchaseOrderProcess"
  targetNamespace="http://acme.com/ws-bp/purchase"
```

```
...
```

```
  <partners>
    <partner name="customer"
      serviceLinkType="lns:purchaseLT"
      myRole="purchaseService"/>
```

```
...
```

```
  </partners>
```

```
  <containers>
```

```
    <container name="PO" messageType="lns:POMessage"/>
```

```
    <container name="Invoice"
      messageType="lns:InvMessage"/>
```

```
...
```

```
  </containers>
```

```
  <faultHandlers>
```

```
    <catch faultName="lns:cannotCompleteOrder"
      faultContainer="POFault">
```

```
      <reply partner="customer"
        portType="lns:purchaseOrderPT"
        operation="sendPurchaseOrder"
        container="POFault"
        faultName="cannotCompleteOrder"/>
```

```
    </catch>
```

```
  </faultHandlers>
```

```
...
```

This section defines the different parties that interact with the business process in the course of processing the order.

This section defines the data containers used by the process, providing their definitions in terms of WSDL message types.

This section contains fault handlers defining the activities that must be executed in response to faults.

# BPEL4WS

## An Example – The process

...

```
<sequence>
```

```
  <receive partner="customer"
    portType="lns:purchaseOrderPT"
    operation="sendPurchaseOrder"
    container="PO">
```

```
  </receive>
```

```
  <flow>
```

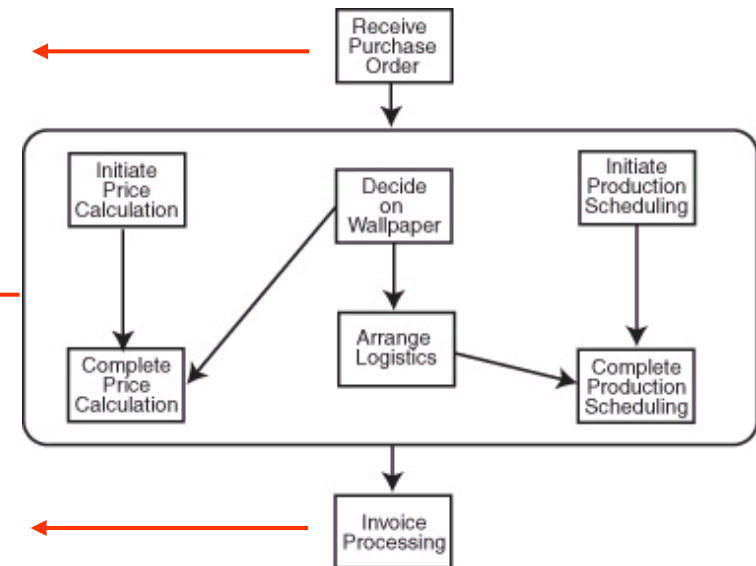

```
    ...
```

```
  </flow>
```

```
  <reply partner="customer"
    portType="lns:purchaseOrderPT"
    operation="sendPurchaseOrder"
    container="Invoice" />
```

```
</sequence>
```

```
</process>
```

# BPEL4WS

## An Example – The process

<flow>

The flow construct provides concurrency and synchronization

```
<links>
  <link name="ship-to-invoice"/>
  <link name="ship-to-scheduling"/>
</links>
```

<sequence> Activities are executed sequentially

...

```
<invoke partner="shippingProvider"
  portType="lms:shippingPT"
  operation="requestShipping"
  inputContainer="shippingRequest"
  outputContainer="shippingInfo">
  <source linkName="ship-to-invoice"/>
</invoke>
```

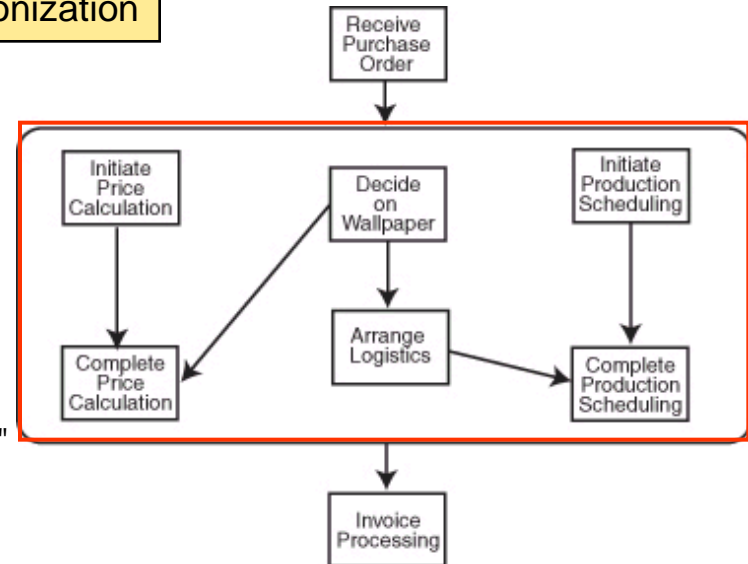

Activity Call

```
<receive partner="shippingProvider"
  portType="lms:shippingCallbackPT"
  operation="sendSchedule"
  container="shippingSchedule">
  <source linkName="ship-to-scheduling"/>
</receive>
</sequence>
```

Activity call

...

</flow>

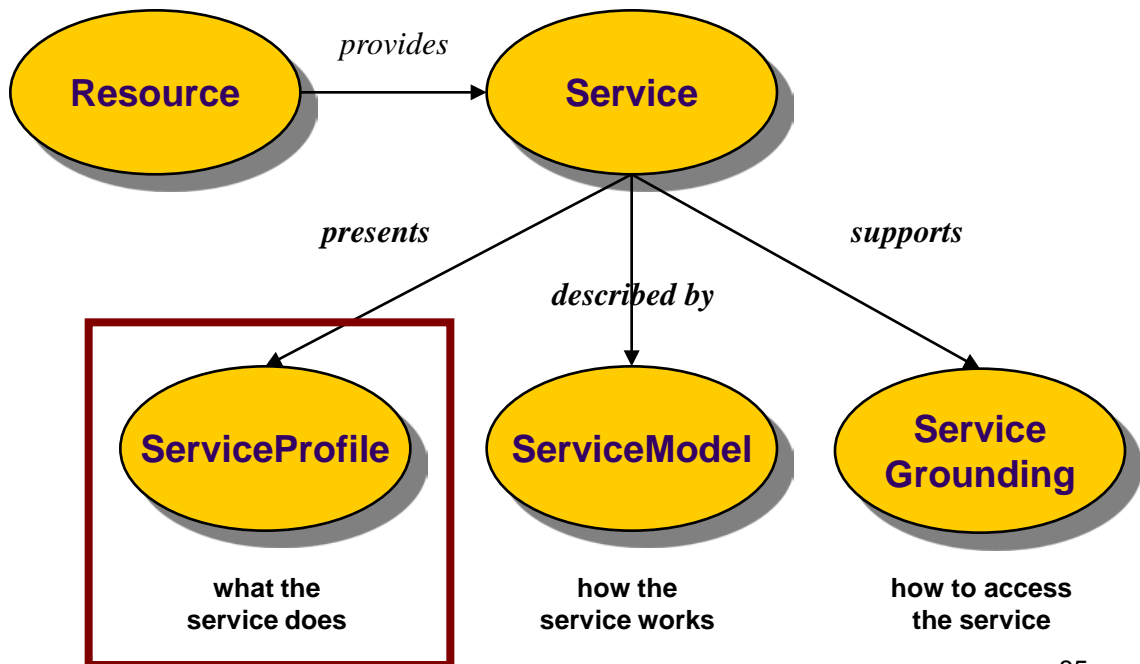

- DAML-S
  - DAML (DARPA Agent Markup Language)
  - DAML-S: Upper ontology of web services
- DAML-S provides support for the following elements:
  - Process description.
  - Advertisement and discovery of services.
  - Selection, composition & interoperation.
  - Invocation.
  - Execution and monitoring.

# DAML-S

## Ontologies

- DAML-S defines ontologies for the construction of service models:
  - Service Profiles
  - Process Models
  - Service Grounding

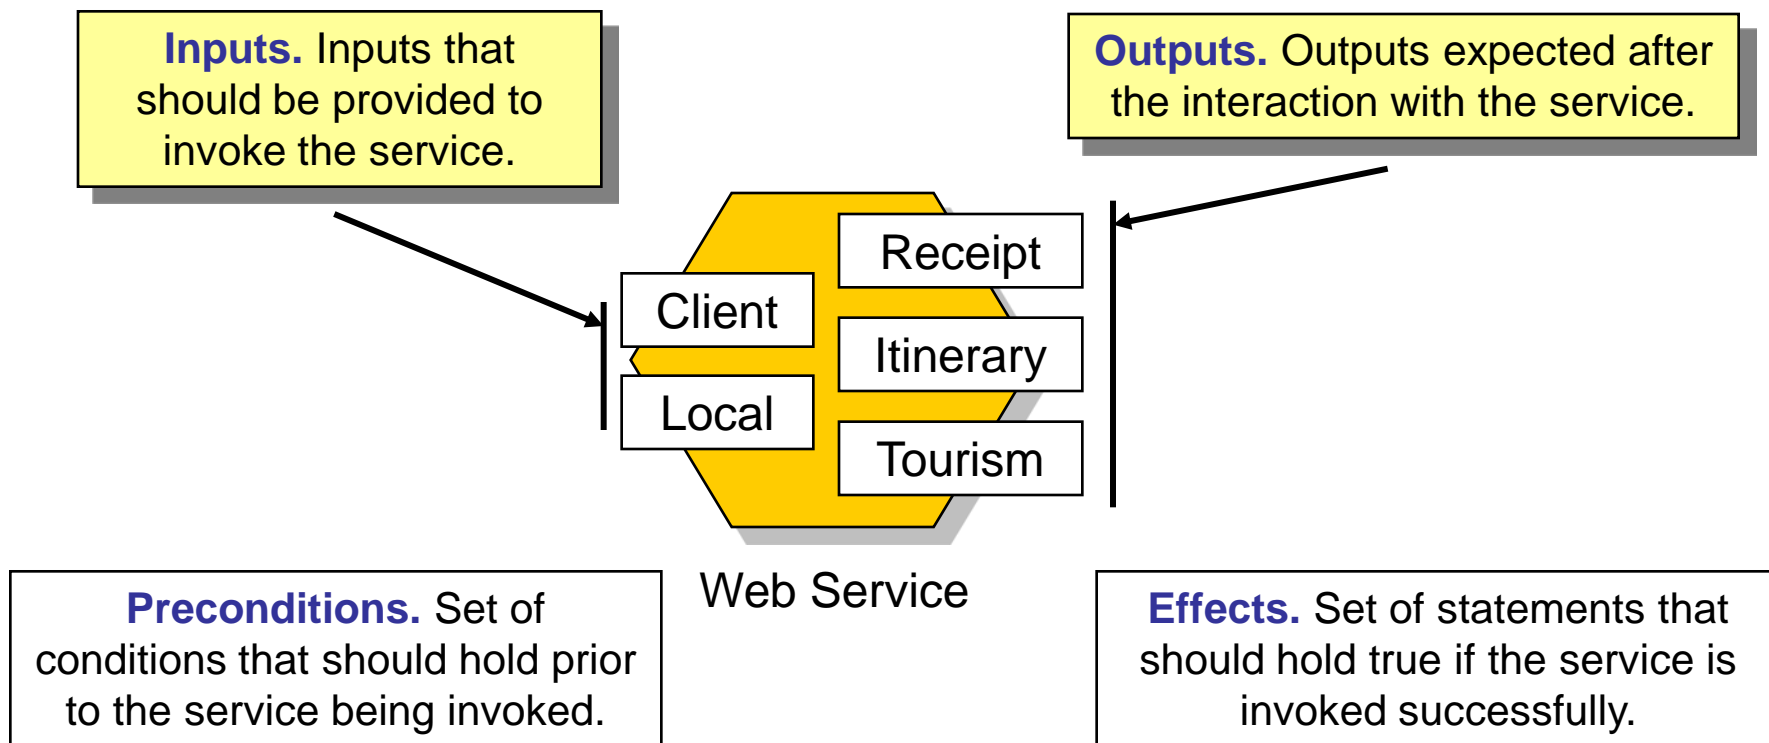

# DAML-S

## Service Profile

The Service Profile provides details about a service.

# Service Profile

## An example of Inputs and Outputs

```

# BPEL4WS vs. DAML-S

## Comparison

- BPEL4WS relates closely to the ServiceModel (Process Model) component of DAML-S.
- DAML-S defines preconditions and effects
  - This enables the representation of side effects of Web services.
  - It also enables a better reasoning about the composition of services.
- DAML-S classes provide a richer representation of services
  - Classes allow reasoning draw properties from inheritance and other relationships to other DAML-S classes.

# BPEL4WS vs. DAML-S

## Comparison

- The DAML-S ServiceProfile and ServiceModel provide sufficient information to enable
  - The automated discovery, composition, and execution based on well-defined descriptions of a service's inputs, outputs, preconditions, effects, and process model.
- BPEL4WS has **complicated semantics** for determining whether an activity actually happens in a block.
- BPEL4WS defines mechanisms for **catching** and **handling faults** and for setting compensation handlers.
- BPEL4WS includes **WS-Coordination** and **WS-Transaction** to provide a context for pre-defined transactional semantics.

**Organizations operating in modern markets, such as e-commerce activities, require QoS management.**

**QoS management is indispensable for organizations striving to achieve a higher degree of competitiveness.**

# Discovery

## New Requirements

- The autonomy of Web services does not allow for designer to identify their operational metrics at design time.
- Nevertheless, when composing a process it is indispensable to inquire the Web services operational metrics.
- Operational metrics characterize the Quality of Service (QoS) that Web services exhibit when invoked.

# QoS

## New Requirements

## Quality of Service

Before

Now

Time?  
Cost?  
Reliability?  
Fidelity?

# QoS Semantics

QoS

- ❑ **What ?**  
Formally describes operational metrics of a web service/process
- ❑ **Why ?**  
To select the most suitable service to carry out an activity in a process
- ❑ **How ?**  
Using QoS model for web services

# QoS Benefits

QoS

- **Composition** of processes according to QoS objective and requirements.
- **Selection and execution** of processes based on QoS metrics.
- **Monitoring** of processes to assure compliance with initial QoS requirements.
- **Evaluation** of alternative strategies when QoS requirements are violated.

# Semantic WP QoS

## Research Issues

QoS

**Specification.** What dimensions need to be part of the QoS model for processes?

**Computation.** What methods and algorithms can be used to compute, analyze, and predict QoS?

**Monitoring.** What kind of QoS monitoring tools need to be developed?

**Control.** What mechanisms need to be developed to control processes, in response to unsatisfactory QoS metrics?

# Web Services

## QoS Specification

QoS

- Operational Metrics Specification
  - Operational metrics are described using a QoS model represented with a suitable ontology.
- The specification of Web services operational metrics allows the analysis and computation processes QoS.
- Processes can be designed according to QoS objectives and requirements.
- This allows organizations to translate their strategies into their processes more efficiently.

# QoS Models

QoS

A QoS Model describes **non-functional** properties of a process

Which dimensions should be part of a QoS model?

# QoS Models and Semantics

QoS

Z#\$%&/

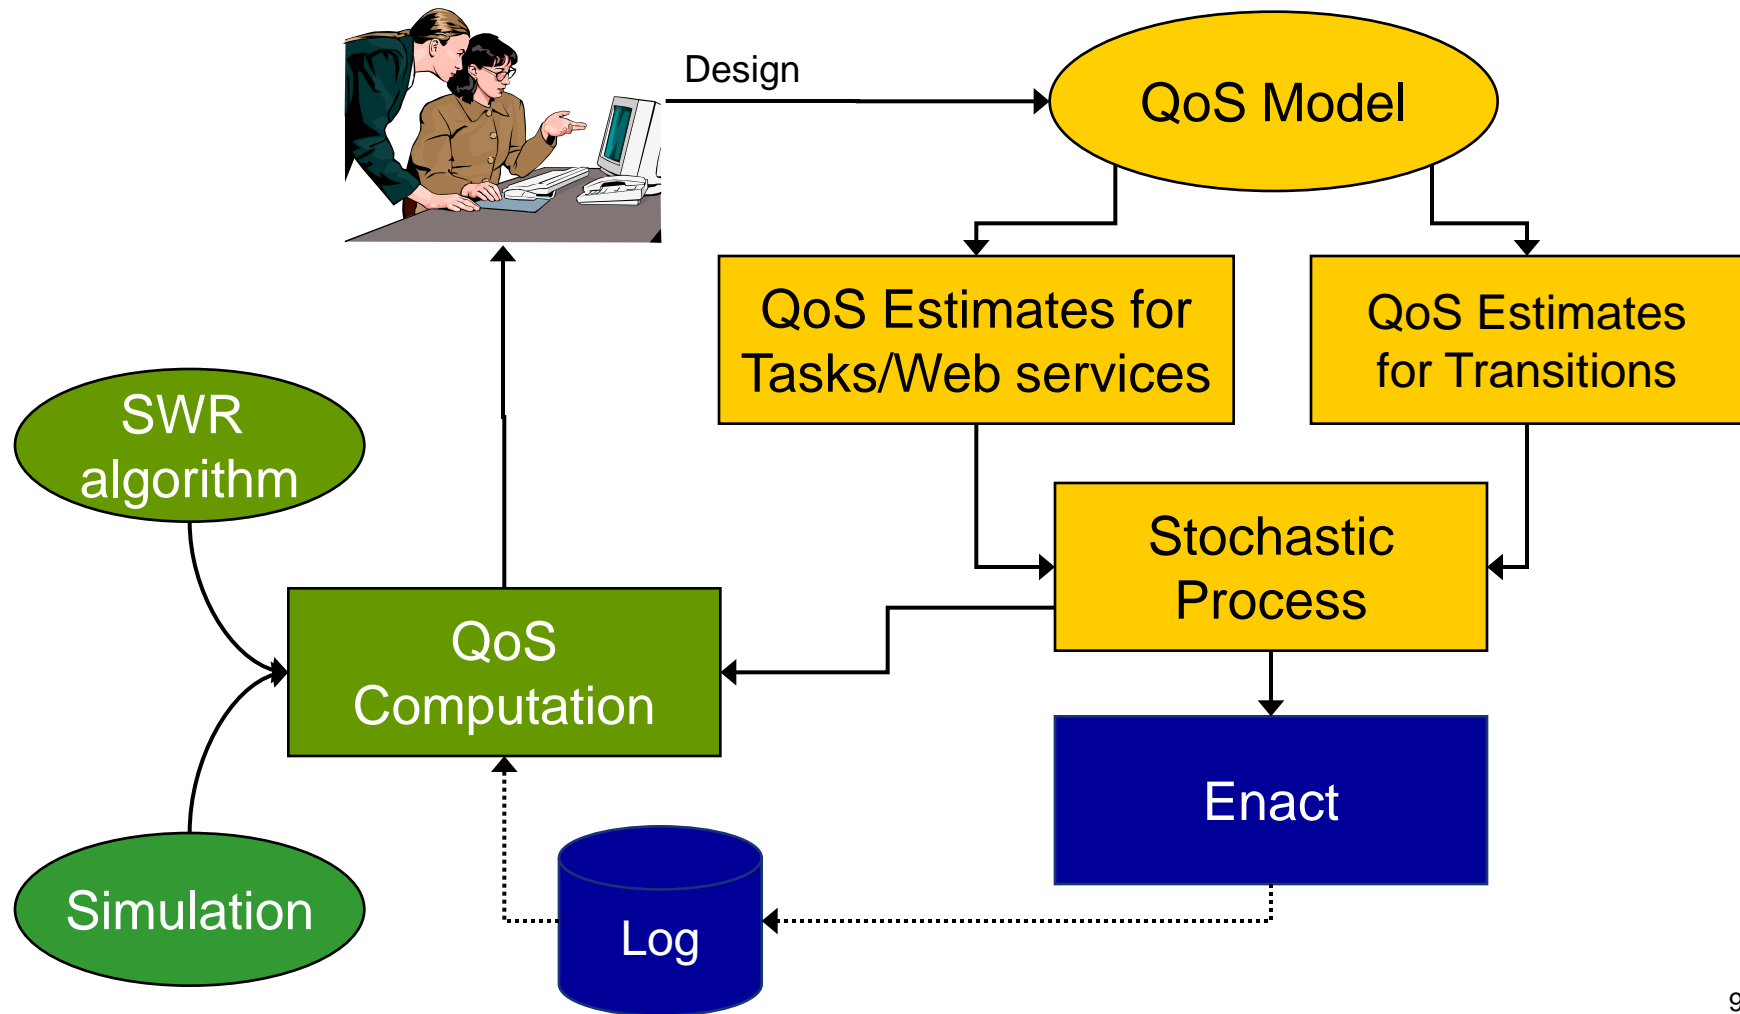

## Use Semantics

# QoS in METEOR-S

QoS

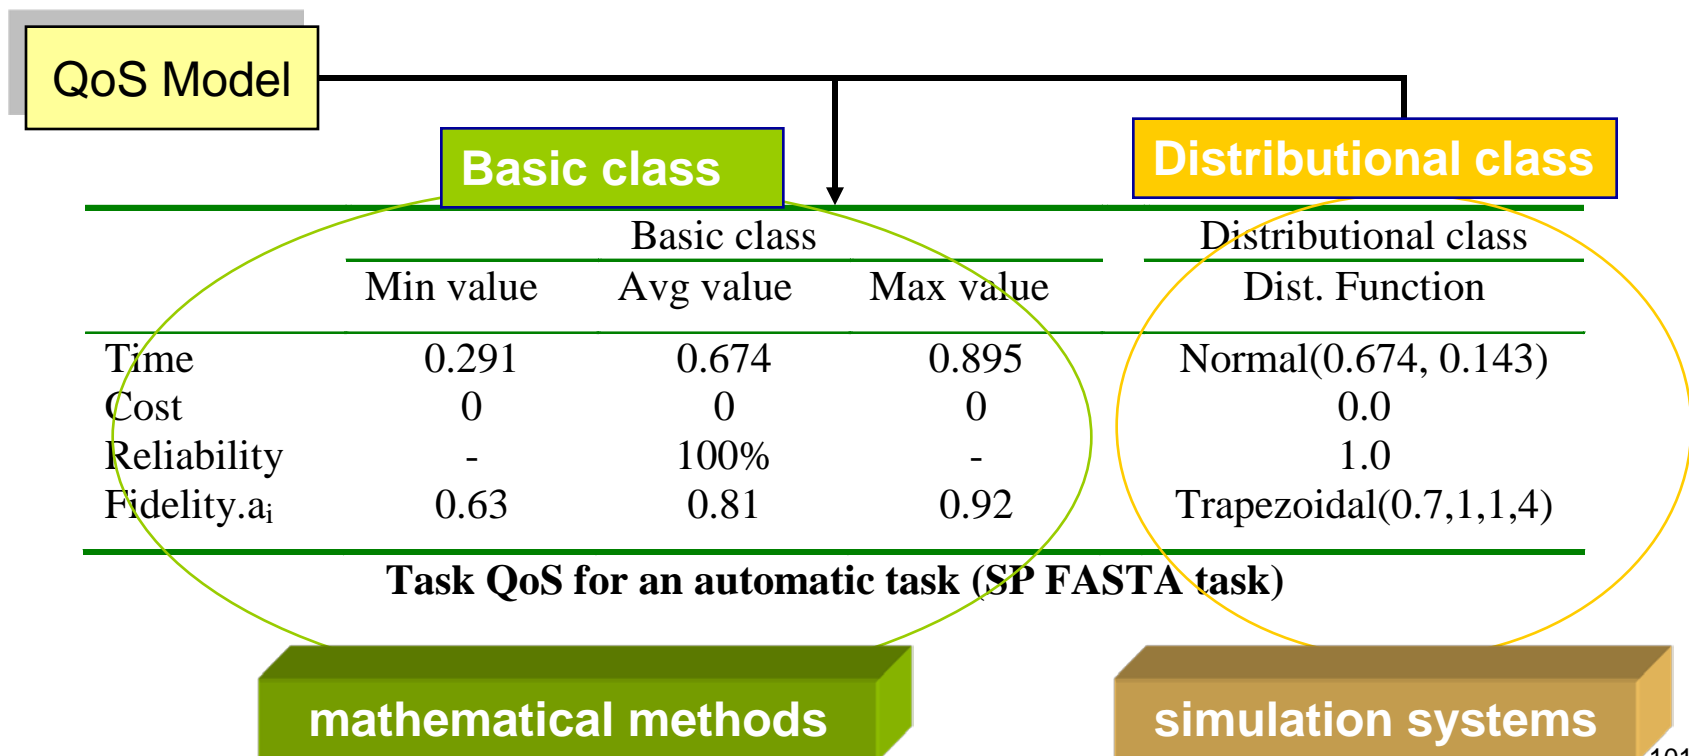

- To analyze a process QoS, it is necessary to:
  - ❑ Create estimated for task QoS metrics and
  - ❑ Create estimated for transition probabilities

Once tasks and transitions have their estimates set, algorithms and mechanisms, such as simulation, can be applied to compute the overall QoS of a process.

**WS runtime behavior description can be composed of several classes. For example:**

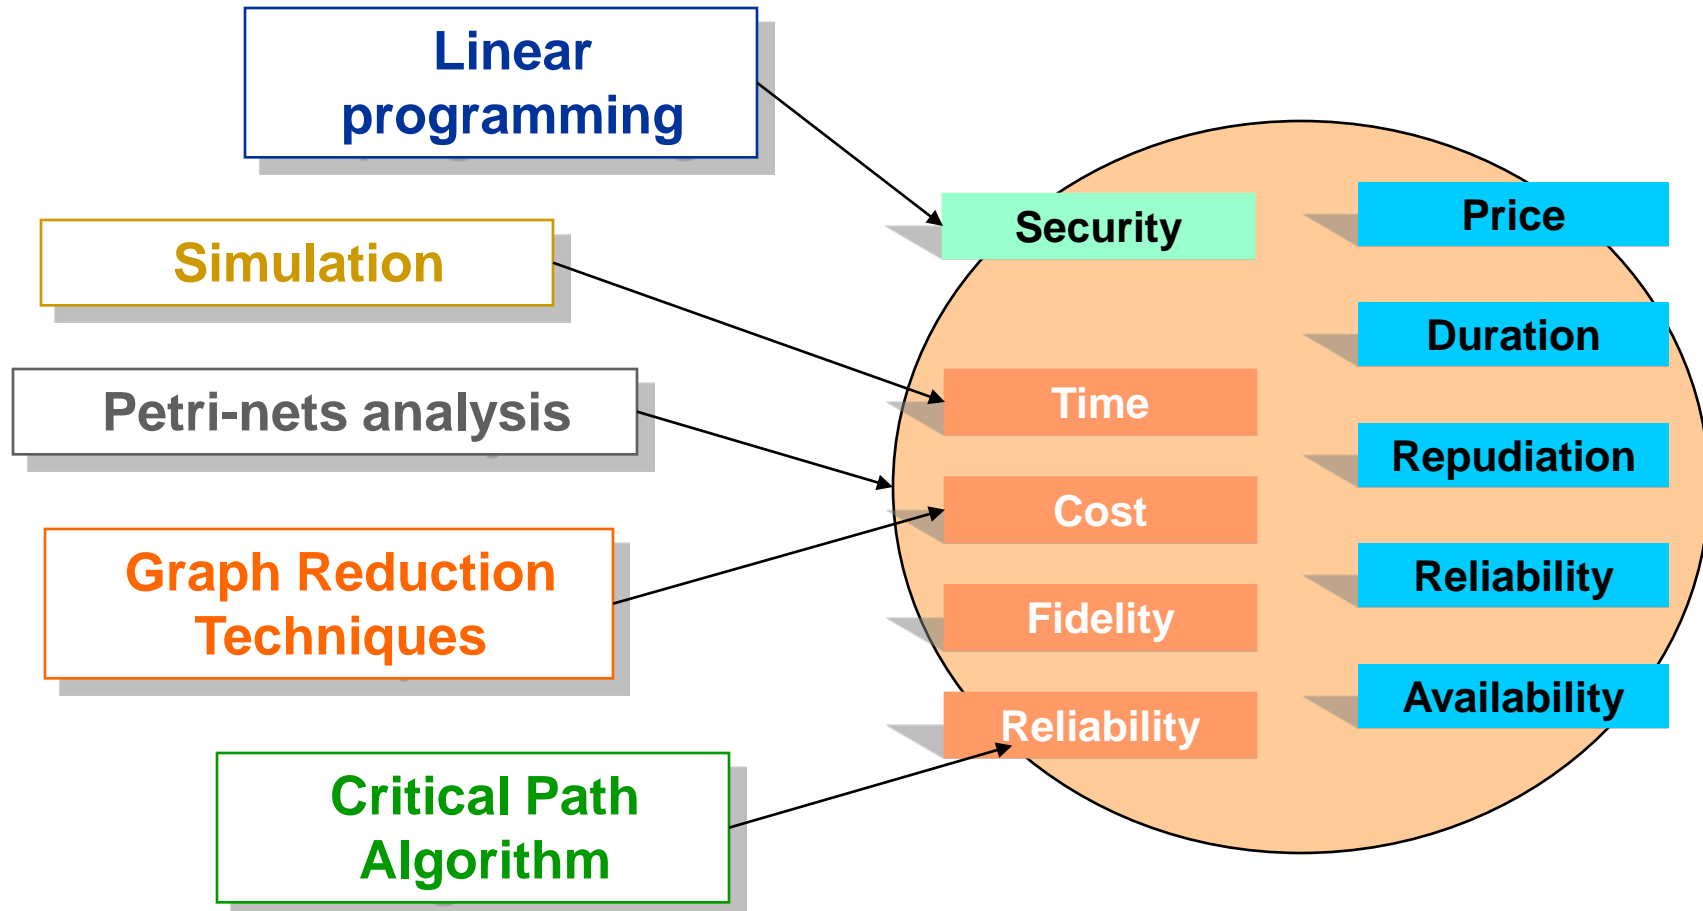

# Web process QoS computation

QoS

Design time| Runtime

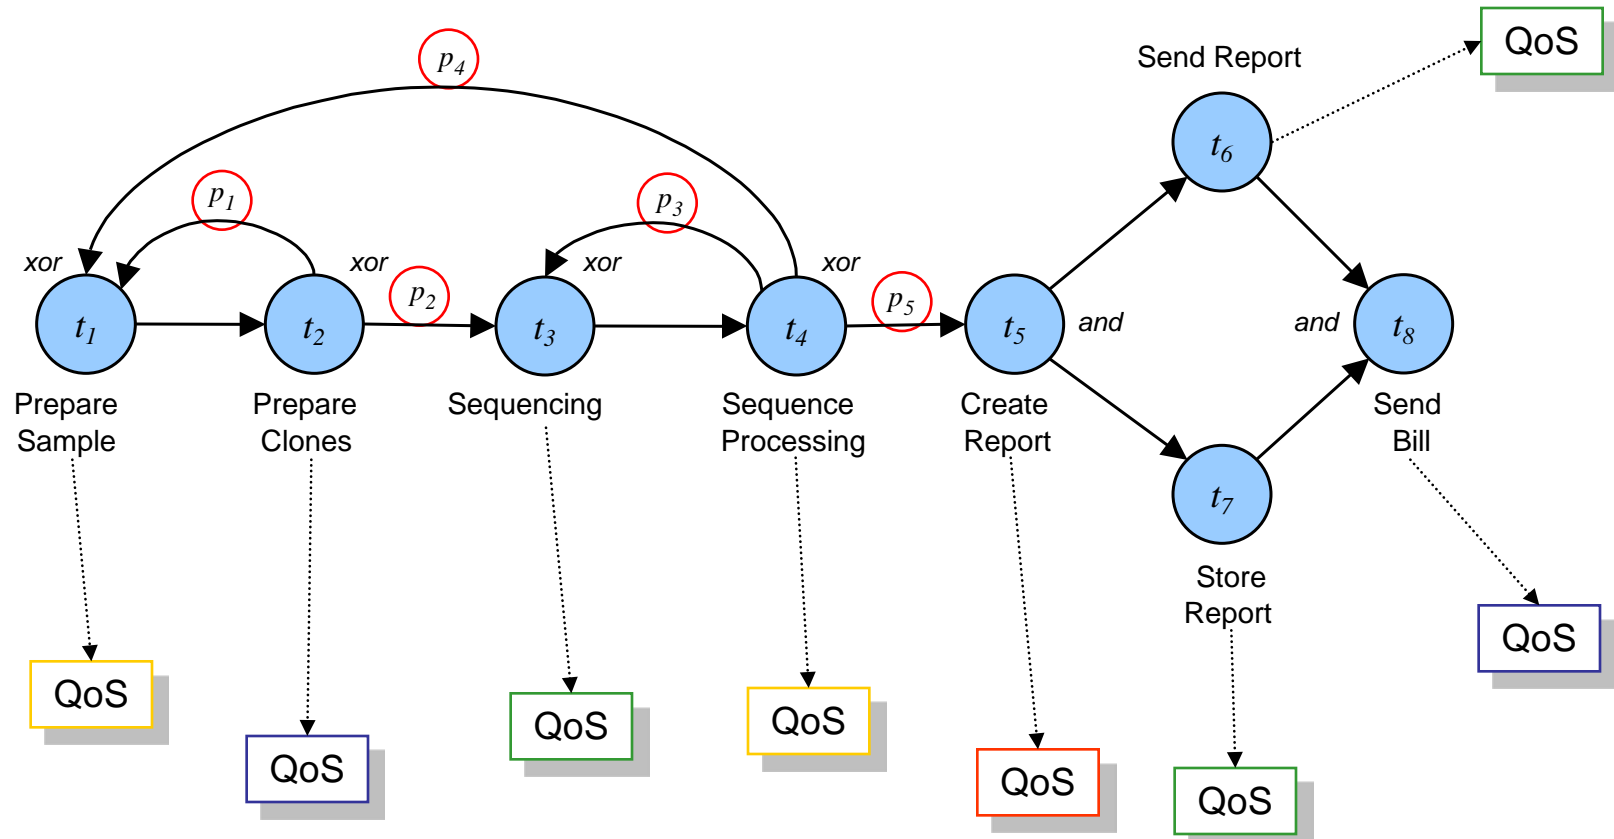

# QoS Computation

QoS

Graph Reduction  
Technique

# QoS Computation

QoS

Graph Reduction  
Technique

(a)

(b)

**Reduction of a  
Sequential System**

---

$$T(t_{ij}) = T(t_i) + T(t_j)$$

$$C(t_{ij}) = C(t_i) + C(t_j)$$

$$R(t_{ij}) = R(t_i) * R(t_j)$$

$$F(t_{ij}).a_r = f(F(t_i), F(t_j))$$

---

# QoS Computation

QoS

Graph Reduction  
Technique

Reduction of a  
Parallel System

$$T(t_{1n}) = \text{Max}_{I \in \{1..n\}} \{T(t_i)\}$$

$$C(t_{1n}) = \sum_{1 \leq i \leq n} C(t_i)$$

$$R(t_{1n}) = \prod_{1 \leq i \leq n} R(t_i)$$

$$F(t_{1n}).a_r = f(F(t_1), F(t_2), \dots, F(t_n))$$

# QoS Computation

QoS

Simulation

- While mathematical methods can be effectively used, another alternative is to utilize **simulation analysis**<sup>1</sup>.
- Simulation can play an important role in tuning the QoS metrics of processes by exploring “**what-if**” questions.
- In our project, these capabilities involve a loosely-coupled integration between the METEOR WfMS and the JSIM simulation system<sup>2</sup>.

# Semantic Web Processes

## Questions?

**NEXT:** METEOR-S Project @ LSDIS lab

# Systems and Applications

## METEOR-S Project @ LSDIS lab

# **METEOR-S** Project @ LSDIS lab

- METEOR-S exploits Workflow, Semantic Web, Web Services, and Simulation technologies to meet these challenges in a practical and standards based approach.
  - Applying Semantics in Annotation, Quality of Service, Discovery, Composition, Execution of Web Services
  - Adding semantics to different layers of Web services conceptual stack
  - Use of ontologies to provide underpinning for information sharing and semantic interoperability

# METEOR-S components for Semantic Web Services

- **Discovery Infrastructure (MWSDI)**
  - Semantic Annotation and Discovery of Web Services <sup>1</sup>
  - Semantic Peer-to-Peer network of Web Services Registries <sup>2</sup>
- **Composer**
  - SCET: Service Composition and Execution Tool <sup>3</sup>
  - **Semantics Process Template Builder and Process Generator** <sup>4</sup>
  - QoS Management
    - Specify, compute, monitor and control QoS (SWR algorithm) <sup>5</sup>
- **Orchestrator** (Under development)
  - Analysis and Simulation <sup>6</sup>
  - Execution
  - Monitoring <sup>6</sup>

# Ongoing Projects

- **SWAP:** <http://swap.semanticweb.org/>
  - Share knowledge effectively
  - Combination of Semantic Web and P2P
- **WonderWeb:** <http://wonderweb.man.ac.uk/>
  - Development of a framework of techniques and methodologies that provide an engineering approach to the building and use of ontologies.
  - Development of a set of foundational ontologies covering a wide range of application domains.
  - Development of infrastructures and tool support that will be required by real world applications in the Semantic Web.

# Ongoing Projects

- **DAML-S:** <http://www.daml.org/services/>
  - Set of ontologies to describe functionalities of web services
- **DAML-S Matchmaker:** [http://www-2.cs.cmu.edu/%7Esoftagents/daml\\_Mmaker/daml-s\\_matchmaker.htm](http://www-2.cs.cmu.edu/%7Esoftagents/daml_Mmaker/daml-s_matchmaker.htm)
  - Match service requestors with service providers
  - Semantic Matchmaking for Web Services Discovery
- **Web Service Composer:** <http://www.mindswap.org/~evren/composer/>
  - Semi-automatic process for the dynamic composition of web services
- **Web Services:** <http://www-106.ibm.com/developerworks/webservices/>
  - WSDL, UDDI, SOAP
  - Business Process with BPEL4WS

# Conclusions

# Conclusions

- Semantic Web service Annotation and Discovery
  - Data semantics
  - Functional semantics
  - QoS Semantics
- Web processes vs. Semantic Web processes
  - BPEL4WS vs. DAML-S
- Web process composition
  - Web services semantic degree of integration
  - Data, Functional, and QoS similarity
- Web process QoS computation
  - QoS Models, techniques, and algorithms

# Conclusions

- **Present Problems in Process Composition**
  - Static discovery of Web Services
  - Design/deployment-time binding of Web services
  - Process Composition is based on interfaces of participating services
- **Proposition**
  - Semantics is the enabler to address the problems of scalability, heterogeneity (syntactic and semantic), machine understandability faced by Web services
- **Semantics for Web Services**
  - Semantics can be applied to different layers of Web Services conceptual stack
  - Semantics for Web Services can be categorized into at least 4 different dimensions namely Data, Functional, Execution and Quality (QoS).

# Conclusions

- Semantics can help address big challenges related to scalability, dynamic environments.
- But comprehensive approach to semantics will be needed:
  - Data/information, function/operation, execution, QoS
- Semantic (Web) principles and technology bring new tools and capabilities that we did not have in EAI, workflow management of the past
